

## PhD Fellowship Position in Remote sensing of Water Quality

A 3-year PhD fellowship is proposed by the Laboratory of Oceanology and Geosciences LOG (Wimereux, France) on the water quality variability by multi-sensors remote sensing in an Inland water/estuarine/deltaic environments. Application to 1) Hauts-de-France watershed up to estuaries and 2) Lower Mekong watershed up to the delta.

### Objectives

Multisensor remote sensing techniques are crucial for understanding the functioning of marine, coastal/littoral and inland water systems as it is a synoptic technique useful to improve our understanding of water quality across the Continental/Sea continuum. Water quality variables that can be assessed by multispectral satellites are turbidity, chlorophyll (an indicator of phytoplankton biomass, trophic and nutritional status), colored dissolved organic matter (an indicator of organic matter and aquatic carbon), suspended solids and non-algal particles. The variable, surface water temperature, is also considered as a good indicator of the environment in term of biodiversity/climate change and species migration corridor with well-defined thermal trajectories. However, the Tonlé Saplake (Cambodia) has never been analyzed concomitantly with other variables, which greatly limits our understanding of the phenomena where water masses are extremely dynamics and vary from nothing to nothing in composition and quantity to within half an hour! Via well-adapted algorithms and appropriated sensors (TRISHNA, Landsat, Sentinel, hyperspectral Unmanned Aerial Vehicule (UAV), etc.), handled images enable us to complete and densify the observations for better management of the territories, in this case here 1) the Hauts- de-France and 2) the Lower Mekong (VolTransMESKONG CNES project & Vietnam- France joint laboratory LOTUS). Indeed, the water quality parameters (WQP) are useful for the evaluation of the sanitary quality facilitating a fortiori the good management of these spaces from the ecological, economic and also touristic point of view (bathing waters). Through this thesis project, for the Hauts-de-France, the spatial/temporal monitoring of these indicators will, among other things, make it possible to understand the evolution and interactions between water masses and marine and coastal resources (biological and mineral) with a focus on estuaries. For the lower Mekong, climatic and anthropogenic forcings will be apprehended through the spatial/temporal analysis of water quality, its degradation and also the hydro-sedimentary flows from the watershed to the delta.

Qualifications: Master degree in remote sensing or oceanography or environmental sciences

Application closure date: May 4 2023

Position Length: 3-year fellowship from October 2023

Location: The candidate will be located at LOG, 32 avenue Foch, 62930 Wimereux, France

Applicants must submit:

- For application before 04th of May fill the form in ADUM website:  
[https://adum.fr/as/ed/voirproposition.pl?matricule\\_prop=48379&site=adumR](https://adum.fr/as/ed/voirproposition.pl?matricule_prop=48379&site=adumR)
- A detailed CV, including the e-mail and phone number for three references
- A short cover letter explaining the applicant's experience related to the position and motivation

For questions and application's submission, please contact:
